1 Introduction

2 Typing System

Dromedar uses a static, strong and sound typing system – typing errors cannot happen at runtime. It knows primitive and reference types.

2.1 Primitives

There are four primitive types:

- int represents 64-bit 2's complement (signed) integers.
- flt represents 64-bit IEEE-754 standard floating point numbers.
- char represents 8-bit UTF-8 characters.
- bool represents a 1-bit value: true and false.

2.2 Reference Types

Reference Types of type t come in two shapes: t, a strictly non-null reference; and t?, a reference that may be null, where t is considered a subtype of t?.

Splitting up references that way has two advantages: On one hand, it enforces a good coding style and helps find Null pointer bugs before they even appear; on the other hand it accelerates the execution environment by allowing it to skip Null checks when dereferencing an object if it is of a strictly non-null type.

3 Expressions

Because Dromedar has a strong type system, it generally disallows any operations with operands of a non-specified type unless they are explicitly cast to the correct type before. This means that integer and floating point numbers cannot be added, multiplied, etc.

The following table describes precedence and type of all operators:

Operator	Name	Prec.	Assoc.	Types
- !	Unary Negation Logical Negation	100	non-assoc.	int -> int flt -> flt bool -> bool
**	Exponentiation	90	right	int,int -> int flt,flt -> flt
*	Multiplication	80	left	int,int -> int flt,flt -> flt
+,-	Addition Subtraction	70	left	<pre>int,int -> int flt,flt -> flt char,int -> char int,char -> char</pre>
<<,>>,>>	Left Shift Logical Right Shift Arithmetic Right Shift	60	left	int,int -> int
&	Bitwise And	60	left	int,int -> int
٨	Bitwise Xor	50	left	int,int -> int
1	Bitwise Or	40	left	int,int -> int
=,!=,>,<,>=,<=	Comparison	30	non-assoc.	<pre>[int] -> bool [flt] -> bool</pre>
&&	Logical And	20	left	bool,bool -> bool
	Logical Or	10	left	bool,bool -> bool

Consider the following example:

The expression 1+18-18+'a' is well-typed (of type **char**) and gets parsed as ((1+18)-18)+'a' and evaluated to 'b'. 10 - 0.0 on the other hand is not well-typed as - cannot take an **int** and a **flt** operand as arguments.

Comparison operators work differently to other (binary) operators: Instead of comparing just two expressions, Dromedar allows chaining expressions to create one final boolean value: For example, 1 < 2 != 5 >= 5 holds because every single sub-expression (1 < 2, 2 != 5 and 5 >= 5) holds. Every expression is only evaluated once for its side-effect.

Thus, A op B op C is not necessarily semantically equivalent to A op B && B op C.

4 Handling Whitespace

In order to keep the code simple and easy to look at, Dromedar uses significant whitespace: Blocks of code (such as bodies of if) statements, are denoted by adding a level of indentation.

Every line is either empty (this includes lines containing only comments), or it contains code.

If a line contains code, the level of its indentation is determined by its relationship to the previous line and its environment:

Two neighboring lines of code within the same block of code must have exactly matching whitespace characters before their respective code starts. If a following line has a deeper level of indentation, it must match the whitespace characters of the previous line and then add a number of additional whitespace characters (space(s) and/or tab(s)).

A line of code can only have a deeper indentation level of one step compared to the previous line. The first line of code is always a global instruction and as such has the lowest level of indentation. If it is indented, this level of indentation corresponds to a baseline indentation that every line of code must share.

Consider this valid example:

Blocks with the same level of indentation can have different indentation strings, but they must still match their environments, as follows:

```
if <condition>
BLOCK A
else
BLOCK B
```

The two blocks have a different indentation level, but from context it is still clear that BLOCK A is a sub-block of the if-statement, whereas BLOCK B belongs to the else-statement.

5 Buildup of a Program

A program consists of a series of global statements – global variable declarations and function definitions.

5.1 Global Declarations

Global variables are all assigned a value at the point of their declaration. This value is evaluated statically – declaration expressions can only contain literals and global variables that were already declared previously.

6 Bytecode

Dromedar can be translated to bytecode for a stack-based virtual machine. It features the following instruction set:

7 Formal Grammar

7.1 Lexer Grammar

The Lexer Grammar is specified using **regular expressions**:

```
LiteralInt ::= /[1-9]\d*/
LiteralFlt ::= /\d+\.\d+/
LiteralChar ::= /'([^'\\]|(\\[\\nrt']))'/
LiteralBool ::= /true|false/
Identifier ::= /[a-zA-Z][a-zA-Z0-9_]*/
           ::= /global/
global
           ::= /fn/
fn
           ::= /let/
let
           ::= /mut/
mut
int
           ::= /int/
flt
           ::= /flt/
char
           ::= /char/
bool
           ::= /bool/
           ::= /void/
void
if
           ::= /if/
elif
           ::= /elif/
else
           ::= /else/
           ::= /do/
do
           ::= /while/
while
return
           ::= /return/
Dash
           ::= /\-/
           ::= /!/
Bang
           ::= /\*/
Star
Plus
           ::= /\+/
LShift
           ::= /<</
RShift
           ::= />>/
           ::= />>>/
AShift
Bitand
           ::= /&/
Xor
           ::= /\^/
Bitor
           ::= /\|/
Logand
           ::= /&&/
Logor
           ::= /\|\|/
Equal
           ::= /=/
NotEqual
           ::= /!=/
           ::= />/
Greater
Less
           ::= /</
GreaterEq
           ::= />=/
LessEq
           ::= /<=/
Assign
           ::= /:=/
           ::= /:/
Colon
           ::= /\->/
Arrow
Comma
           ::= /\,/
LParen
           ::= /\(/
           ::= /\)/
RParen
```

7.2 Parser Grammar

The following grammar specification uses a preceding % for lexer tokens.

Program ::= | €

GlobalStatement Program

GlobalStatement ::=

| GVDeclaration | GFDeclaration

GVDeclaration ::=

| %Global %Identifier %Assign GlobalExpression

GFDeclaration ::=

FArguments ::=

| %Identifier %Colon Type

| %Identifier %Colon Type %Comma FArguments

ReturnType ::=
